

**Part 3**

# lesson

# 1

## Thermometer

## Overview

In this lesson, you will use an LCD display to show the temperature.

### Component Required:

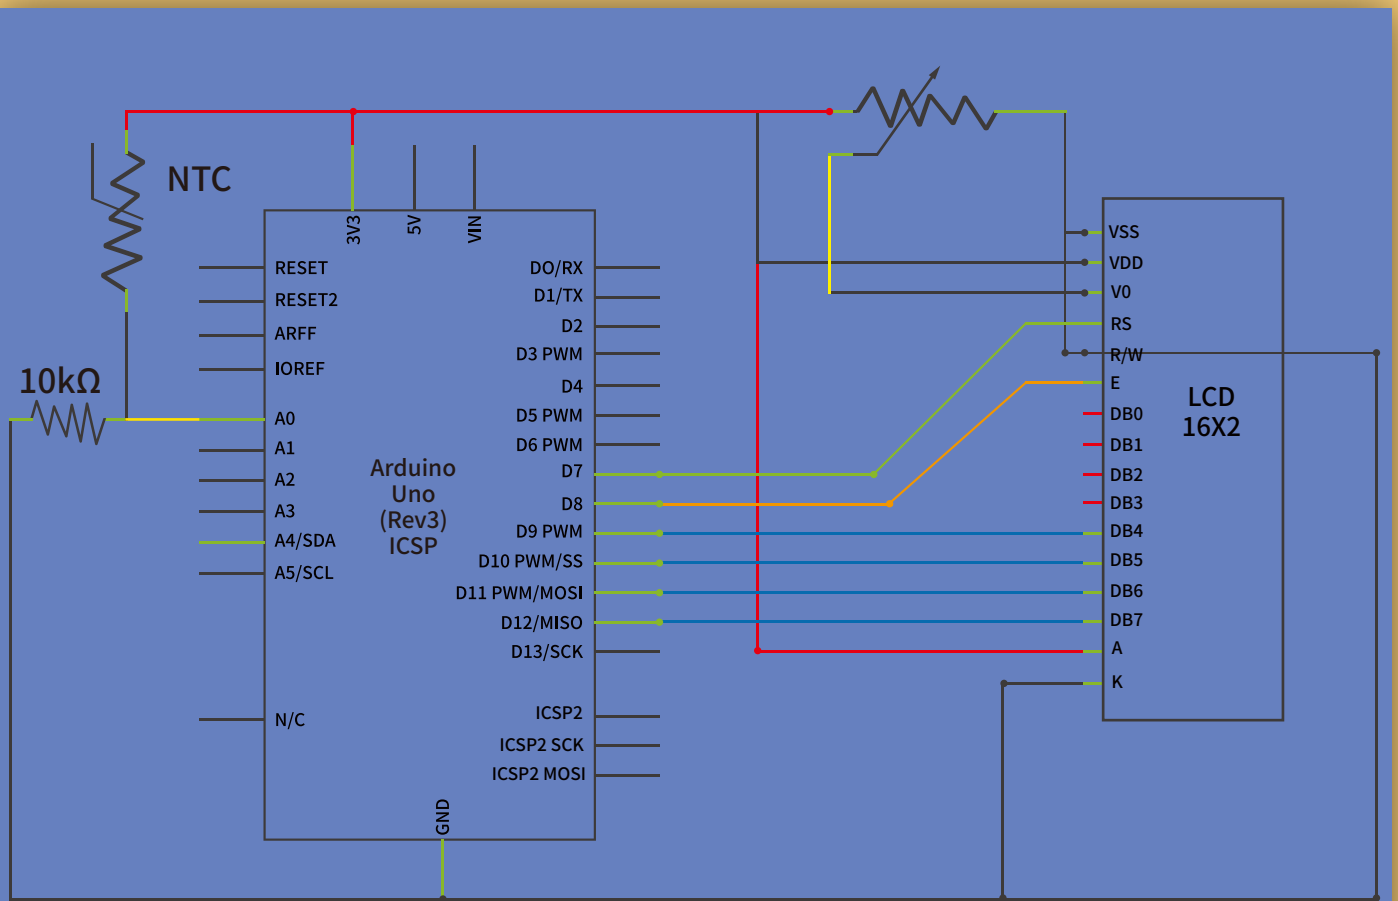

- (1) x Elegoo Uno R3
- (1) x LCD1602 Module
- (1) x 10k ohm resistor
- (1) x Thermistor
- (1) x Potentiometer
- (1) x 830 tie-points Breadboard
- (18) x M-M wires (Male to Male jumper wires)

## Component Introduction

### Thermistor

- A** thermistor is a thermal resistor - a resistor that changes its resistance with temperature. Technically, all resistors are thermistors - their resistance changes slightly with temperature - but the change is usually very small and difficult to measure. Thermistors are made so that the resistance changes drastically with temperature. It can be 100 Ohms or more, per degree of change.
- There** are two kinds of thermistors, NTC (negative temperature coefficient) and PTC (positive temperature coefficient). In general, you will see NTC sensors used for temperature measurement. PTC's are often used as resettable fuses - an increase in temperature increases the resistance which means that as more current passes through them, they heat up and 'choke back' the current, quite handy for protecting circuits!

## Connection Schematic

There are a few jumper wires near the pot that have been moved slightly on this layout.

The 10 kΩ resistor and thermistor are all new additions to the board.

**Wiring diagram**

## Code

After wiring, please open the program in the code folder- **Thermometer** and click UPLOAD to upload the program. See Lesson 5 of part 1 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the **< LiquidCrystal >** library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson 5 of part 1.

```
//      BS E D4 D5 D6 D7
LiquidCrystal lcd( 7, 8, 9, 10, 11, 12);
```

Load it up onto your Arduino and you should find that warming the temperature sensor by putting your finger on it will increase the temperature reading.

This makes things easier if you decide to change which pins you use.

In the 'loop' function there are now two interesting things going on. Firstly we have to convert the analogue from the temperature sensor into an actual temperature, and secondly we have to work out how to display them.

First of all, let's take a look at calculating the temperature.

```
int tempReading = analogRead(tempPin);
double tempK = log(10000.0 * ((1024.0 / tempReading - 1)));
tempK = 1 / (0.001129148 + (0.000234125 + (0.0000000876741 * tempK * tempK))
* tempK);
float tempC = tempK - 273.15;
float tempF = (tempC * 9.0) / 5.0 + 32.0;
```

Displaying changing readings on an LCD display can be tricky. The main problem is that the reading may not always be the same number of digits. So, if the temperature changed from 101.50 to 99.00 then the extra digit from the old reading is in danger of being left on the display.

To avoid this, write the whole line of the LCD each time around the loop.

The rather strange comment serves to remind you of the 16 columns of the display.

```
lcd.setCursor(0, 0); lcd.print("Temp  C      ");
lcd.setCursor(6, 0);
lcd.print(tempF);
```

You can then print a string of that length with spaces where the actual reading will go.

To fill in the blanks, set the cursor position for where the reading should appear and then print it.
